ABURide — Project Summary

At Ahmadu Bello University, students constantly face long delays and forced trekking because shuttle drivers do not know exactly where they are waiting. Meanwhile, drivers waste expensive fuel driving empty routes, hoping to stumble upon passengers. They sometimes wait idle at stops where there are no passengers, while so many frustrated students are waiting for a bus at another bus stop across the campus. This daily information gap hurts both sides severely and decreases overall transit efficiency every single morning.

To solve this exact problem, I built ABURide, a highly efficient, real-time matchmaking system. Instead of forcing students to download a heavy new app, they simply use a Telegram bot. A student taps a button to say, "I am at the Main Gate." Drivers check a simple, color-coded dashboard on their phones showing exactly where the biggest crowds are located. When a driver taps "Accept Route," the waiting students instantly receive a message that their bus is on the way. It guarantees drivers always find passengers, and students are never left guessing.

While highly effective for a university, I would not trust this prototype to run complex city-wide public transit, process financial payments, or store highly sensitive personal data. It is a targeted, lightweight tool designed strictly to solve movement within a closed campus environment.

Module 3.1: Mastering AI Prompts for Any Task from the Meta x 3MTT x RAIN AI Academy program was the most helpful part of my training. Using the excellent techniques from this module, I was able to precisely prompt Large Language Models to help me research the most efficient software architecture, write the core application code, and debug complex errors with absolute pinpoint accuracy. This directly allowed me to build and refine a highly reliable, investor-ready product incredibly fast and seamlessly without any major issues.
